## 2 Simple Linear Regression: Normal Homoskedastic Error Case

- Assumptions
- Least Squares

# Bias and Mean Squared Error (MSE)

Def.  
Let  $\hat{\theta}$  be an estimator of parameter  $\theta$  of some distribution. Then

- *Bias* of the estimator is defined as

$$\text{Bias} = \text{E}[\hat{\theta} - \theta].$$

- *Mean Squared Error* (MSE) of the estimator is defined as

$$\text{MSE} = \text{E} \left[ \left( \hat{\theta} - \theta \right)^2 \right].$$

# Bias and Mean Squared Error (MSE)

Def.

Let  $\hat{\theta}$  be an estimator of parameter  $\theta$  of some distribution. Then

- *Bias* of the estimator is defined as

$$\text{Bias} = \text{E}[\hat{\theta} - \theta].$$

- *Mean Squared Error* (MSE) of the estimator is defined as

$$\text{MSE} = \text{E} \left[ \left( \hat{\theta} - \theta \right)^2 \right].$$

Thm.

Let  $\hat{\theta}$  be an estimator of  $\theta$ . Then

$$\text{MSE} = \text{Bias}^2 + \text{Var}(\hat{\theta}).$$

# Consistency of Parameter Estimators

Def.

Let  $\hat{\theta}_n$  be an estimator of a parameter  $\theta$  of some distribution based on a sample of i.i.d.  $X_1, X_2, \dots, X_n$  from this distribution.

$\hat{\theta}_n$  is called *consistent* (or *asymptotically consistent*) estimator of  $\theta$  if for any  $\varepsilon > 0$ ,

$$\lim_{n \rightarrow \infty} P(|\hat{\theta}_n - \theta| > \varepsilon) = 0.$$

# MSE and Efficiency

## Recall:

If true value of parameter is  $\theta$ , then the *Mean Squared Error* (MSE) of estimator  $\hat{\theta}$  is defined as

$$\begin{aligned}\text{MSE}(\hat{\theta}) &\doteq \text{E} \left[ (\hat{\theta} - \theta)^2 \right] \\ &= \underbrace{\left( \text{E}[\hat{\theta}] - \theta \right)^2}_{\text{Bias}^2} + \text{Var}(\hat{\theta})\end{aligned}$$

# MSE and Efficiency

## Recall:

If true value of parameter is  $\theta$ , then the *Mean Squared Error* (MSE) of estimator  $\hat{\theta}$  is defined as

$$\begin{aligned}\text{MSE}(\hat{\theta}) &\doteq \text{E} \left[ (\hat{\theta} - \theta)^2 \right] \\ &= \underbrace{\left( \text{E}[\hat{\theta}] - \theta \right)^2}_{\text{Bias}^2} + \text{Var}(\hat{\theta})\end{aligned}$$

## Def.

Estimator  $\tilde{\theta}$  is said to be more *efficient* than  $\hat{\theta}$  if

$$\text{Var}(\tilde{\theta}) < \text{Var}(\hat{\theta}).$$

The ratio  $\text{eff}(\tilde{\theta}, \hat{\theta}) \doteq \text{Var}(\hat{\theta}) / \text{Var}(\tilde{\theta})$  is called *efficiency* of  $\tilde{\theta}$  relative to  $\hat{\theta}$ .

Note:  $\tilde{\theta}$  is more efficient means  $\text{eff}(\tilde{\theta}, \hat{\theta}) > 1$ .

- Pooled Variance
- Proportions: Hypotheses Testing and Confidence Intervals
- Sample Covariance and Sample Correlation

## 2 Simple Linear Regression: Normal Homoskedastic Error Case

- Assumptions
- Least Squares

# Confidence Interval: Example

## Example:

Consider the following random sample from a normal distribution  $N(\mu, \sigma^2)$ :

14.2, 12.1, 15.9, 17.6, 17.4, 18.2   i.e.  $\bar{X} = 15.9$  and  $S = 2.3563$

Suppose we want to estimate  $\mu$ , then  $\mu \approx \bar{X} = 15.9$ .

# Confidence Interval: Example

## Example:

Consider the following random sample from a normal distribution  $N(\mu, \sigma^2)$ :

$$14.2, 12.1, 15.9, 17.6, 17.4, 18.2 \quad \text{i.e. } \bar{X} = 15.9 \text{ and } S = 2.3563$$

Suppose we want to estimate  $\mu$ , then  $\mu \approx \bar{X} = 15.9$ .

Assume we also want to construct 95% *confidence interval* for  $\mu$ , that is, we want

$$P(\bar{X} - \text{ME} < \mu \leq \bar{X} + \text{ME}) = 0.95,$$

then

$$P\left(-\frac{\text{ME}}{S/\sqrt{n}} < \frac{\bar{X} - \mu}{S/\sqrt{n}} \leq \frac{\text{ME}}{S/\sqrt{n}}\right) = 0.95, \text{ i.e. } \text{ME} = t_{0.025, n-1} \frac{S}{\sqrt{n}}.$$

Therefore,

$$\mu = \bar{X} \pm t_{0.025, n-1} \frac{S}{\sqrt{n}} = 15.9 \pm 2.5 \text{ with } 95\% \text{ confidence.}$$

Here,  $t_{0.025, n-1}$  is defined as  $P(T > t_{0.025, n-1}) = 0.025$ , where  $T \sim t_{n-1}$ .

# Confidence Intervals for Mean

## Def.

Given i.i.d. sample  $X_1, X_2, \dots, X_n$  from a distribution with expectation  $\mu$ ,  $(1 - \alpha)100\%$  *confidence interval* for  $\mu$  is defined as

$$\mu = \bar{X} \pm \text{ME},$$

where  $P(\bar{X} - \text{ME} < \mu \leq \bar{X} + \text{ME}) = 1 - \alpha$ .

## Claim:

$(1 - \alpha)100\%$  *confidence interval* for  $\mu$  is given by:

- $\mu = \bar{X} \pm z_{\alpha/2} \frac{\sigma}{\sqrt{n}}$ , if  $\sigma$  is known and data comes from normal
- $\mu = \bar{X} \pm t_{\alpha/2, n-1} \frac{S}{\sqrt{n}}$ , if data comes from normal
- $\mu = \bar{X} \pm z_{\alpha/2} \frac{S}{\sqrt{n}}$ , if  $n$  is large

Here,

$z_{\alpha/2}$  is defined as  $P(Z > z_{\alpha/2}) = \alpha/2$ , where  $Z \sim N(0, 1^2)$ ;

$t_{\alpha/2, n-1}$  is defined as  $P(T > t_{\alpha/2, n-1}) = \alpha/2$ , where  $T \sim t_{n-1}$ .

# Confidence Intervals for Difference between Two Means

## Def.

Given i.i.d. samples  $X_1^{(1)}, X_2^{(1)}, \dots, X_n^{(1)}$  and  $X_1^{(2)}, X_2^{(2)}, \dots, X_n^{(2)}$  from two distributions with expectations  $\mu_1$  and  $\mu_2$ , respectively,  $(1 - \alpha)100\%$  *confidence interval* for  $\mu_1 - \mu_2$  is defined as

$$\mu - \mu_2 = \bar{X}_1 - \bar{X}_2 \pm \text{ME},$$

where  $P(\bar{X}_1 - \bar{X}_2 - \text{ME} < \mu_1 - \mu_2 \leq \bar{X}_1 - \bar{X}_2 + \text{ME}) = 1 - \alpha$ .

## Claim:

$(1 - \alpha)100\%$  *confidence interval* for  $\mu_1 - \mu_2$  is given by:

- $\mu_1 - \mu_2 = \bar{X}_1 - \bar{X}_2 \pm z_{\alpha/2} \sqrt{\frac{\sigma_1^2}{n_1} + \frac{\sigma_2^2}{n_2}}$ , if  $\sigma_1$  and  $\sigma_2$  are known and data comes from normal distributions

- $\mu_1 - \mu_2 = \bar{X}_1 - \bar{X}_2 \pm t_{\alpha/2, \text{d.f.}} \sqrt{\frac{S_1^2}{n_1} + \frac{S_2^2}{n_2}}$ , if data

comes from normal distributions, where  $\text{d.f.} \approx \frac{\left(\frac{S_1^2}{n_1} + \frac{S_2^2}{n_2}\right)^2}{\frac{1}{n_1 - 1} \left(\frac{S_1^2}{n_1}\right)^2 + \frac{1}{n_2 - 1} \left(\frac{S_2^2}{n_2}\right)^2}$

- $\mu_1 - \mu_2 = \bar{X}_1 - \bar{X}_2 \pm z_{\alpha/2} \sqrt{\frac{S_1^2}{n_1} + \frac{S_2^2}{n_2}}$ , if  $n_1$  and  $n_2$  are large

## 1 Review of Statistics (Continued)

  - Bias and Mean Squared Error (MSE)
  - Consistency
  - Efficiency
- Confidence Intervals
  - Example
  - Confidence Intervals for Mean
  - Confidence Intervals for Difference between Two Means
- Pooled Variance
- Proportions: Hypotheses Testing and Confidence Intervals
- Sample Covariance and Sample Correlation

## 2 Simple Linear Regression: Normal Homoskedastic Error Case

- Assumptions
- Least Squares

# Pooled Variance: Difference between Two Means

Assume i.i.d. samples  $X_1^{(1)}, X_2^{(1)}, \dots, X_n^{(1)}$  and  $X_1^{(2)}, X_2^{(2)}, \dots, X_n^{(2)}$  come from two normal distributions with same variance  $\sigma^2$ , then

$$\begin{aligned}\sigma^2 \approx S_p^2 &\doteq \frac{1}{n_1 + n_2 - 2} \left[ \sum_{i=1}^{n_1} (X_i^{(1)} - \bar{X}_1)^2 + \sum_{i=1}^{n_2} (X_i^{(2)} - \bar{X}_2)^2 \right] \\ &= \frac{(n_1 - 1)S_1^2 + (n_2 - 1)S_2^2}{n_1 + n_2 - 2}.\end{aligned}$$

Then

- test statistic for  $H_0 : \mu_1 - \mu_2 = \Delta_0$  vs.  $H_1 : \mu_1 - \mu_2 \neq \Delta_0$  is given by:

$$\text{TS} = \frac{\bar{X}_1 - \bar{X}_2 - \Delta_0}{S_p \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}}, \text{ t-test, } d.f. = n_1 + n_2 - 2$$

- $(1 - \alpha)100\%$  confidence interval for  $\mu_1 - \mu_2$  is given by:

$$\mu_1 - \mu_2 = \bar{X}_1 - \bar{X}_2 \pm t_{\alpha/2, n_1 + n_2 - 2} S_p \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}$$

## 2 Simple Linear Regression: Normal Homoskedastic Error Case

- Assumptions
- Least Squares

# Proportions: Hypotheses Testing and Confidence Intervals

Assume  $X_1, X_2, \dots, X_n$  is an i.i.d. sample from binary distribution consisting of 0's and 1's, then

- $\mu = p$  is proportion
- $\bar{X} = \hat{p}$  is sample proportion
- $\text{Var}(\hat{p}) = \frac{p(1-p)}{n}$

Note that by CLT,  $\hat{p}$  tends to be approximately Normal, because  $\hat{p}$  is the sample mean.

Therefore, if  $n$  is large, one can use z-test and  $z_{\alpha/2}$  critical value, otherwise - Exact Binomial Test.

## 2 Simple Linear Regression: Normal Homoskedastic Error Case

- Assumptions
- Least Squares

# Sample Covariance and Sample Correlation

Def.

Assuming i.i.d. observations  $(X_1, Y_1), (X_2, Y_2) \dots, (X_n, Y_n)$  from a joint distribution, then

- *sample variances* of  $X$  and  $Y$ :

$$s_X^2 \doteq \frac{1}{n-1} \sum_{i=1}^n (X_i - \bar{X})^2 \quad \text{and} \quad s_Y^2 \doteq \frac{1}{n-1} \sum_{i=1}^n (Y_i - \bar{Y})^2$$

- *sample covariance*:

$$s_{XY} \doteq \frac{1}{n-1} \sum_{i=1}^n (X_i - \bar{X})(Y_i - \bar{Y})$$

- *sample correlation coefficient* (or *sample correlation*):

$$r_{XY} = \frac{s_{XY}}{s_X s_Y}$$

# Sample Covariance and Sample Correlation

## Claim:

Assuming i.i.d. observations  $(X_1, Y_1), (X_2, Y_2) \dots, (X_n, Y_n)$  from a joint distribution,

$$s_{XY} \xrightarrow{P} \text{Cov}(X, Y).$$

## Claim:

Assuming i.i.d. observations  $(X_1, Y_1), (X_2, Y_2) \dots, (X_n, Y_n)$  from a joint distribution,

$$r_{XY} \xrightarrow{P} \text{corr}(X, Y).$$

## 2 Simple Linear Regression: Normal Homoskedastic Error Case

- Assumptions
- Least Squares

# Simple Linear Regression: Normal Homoskedastic Error

## Assumptions:

For  $i \in \{1, 2, \dots, n\}$ , let

- $x_i$  be fixed values with  $\min\{x_i\} < \max\{x_i\}$
- $\varepsilon_i \stackrel{\text{iid}}{\sim} N(0, \sigma^2)$ , where  $\sigma^2$  is independent of  $i$  (*homoskedasticity*)
- $y_i = \beta_0 + \beta_1 x_i + \varepsilon_i$

# Simple Linear Regression: Normal Homoskedastic Error

## Assumptions:

For  $i \in \{1, 2, \dots, n\}$ , let

- $x_i$  be fixed values with  $\min\{x_i\} < \max\{x_i\}$
- $\varepsilon_i \stackrel{\text{iid}}{\sim} N(0, \sigma^2)$ , where  $\sigma^2$  is independent of  $i$  (*homoskedasticity*)
- $y_i = \beta_0 + \beta_1 x_i + \varepsilon_i$

## Note:

Given  $x_i$ ,

$y_i \sim N(\beta_0 + \beta_1 x_i, \sigma^2)$  are independent, where  $i \in \{1, 2, \dots, n\}$ .

Then

- One can use, for example, MLE to estimate  $\beta_0$  and  $\beta_1$ .
- Given *predictor*  $x_i$ , the expectation of *response*  $y_i$  is

$$E[y_i] = \beta_0 + \beta_1 x_i.$$

## 1 Review of Statistics (Continued)

- Estimation of Parameters and Fitting of Probability Distributions
  - Bias and Mean Squared Error (MSE)
  - Consistency
  - Efficiency

  - Confidence Intervals for Difference between Two Means
- Pooled Variance
- Proportions: Hypotheses Testing and Confidence Intervals
- Sample Covariance and Sample Correlation

## 2 Simple Linear Regression: Normal Homoskedastic Error Case

- Assumptions
- Least Squares

# Simple Linear Regression: Least Squares

## Claim:

Given a Simple Linear Regression model,

$$y_i = \beta_0 + \beta_1 x_i + \varepsilon_i, \quad \varepsilon_i \stackrel{\text{iid}}{\sim} N(0, \sigma^2), \quad i \in \{1, 2, \dots, n\},$$

the Maximum Likelihood Estimators (MLE's) of  $\beta_0$  and  $\beta_1$  can be equivalently obtained by minimizing the sum of squared residuals,

$$S(\beta_0, \beta_1) = \sum_{i=1}^n (y_i - \underbrace{[\beta_0 + \beta_1 x_i]}_{E[y_i]})^2,$$

and are

$$\hat{\beta}_1 = \frac{\sum_{i=1}^n (x_i - \bar{x})(y_i - \bar{y})}{\sum_{i=1}^n (x_i - \bar{x})^2} \quad \text{and} \quad \hat{\beta}_0 = \bar{y} - \hat{\beta}_1 \bar{x}.$$

## Note:

These estimators are often referred as *ordinary least squares* (OLS) estimators.
