Regression with Panel Data

Terminology: *Panel data* (or *longitudinal data*) consists of observations on the same n entities at two or more time periods T :

$$(X_{it}, Y_{it}), \quad i = 1, 2, \dots, n, \quad \text{and} \quad t = 1, 2, \dots, T,$$

where

i refers to entity and t refers to time at it is observed.

If some observations are missing the panel is called *unbalanced panel*, otherwise - *balanced panel*.

Regression with Panel Data: Entity Fixed Effects Regression

Let's assume that

$$Y_{it} = \beta_0 + \beta_1 X_{it} + \beta_2 Z_i + u_{it},$$

where Z_i is an unobserved variable that depends on i but does not change over time t . Therefore, we can rewrite

$$Y_{it} = \alpha_i + \beta_1 X_{it} + u_{it},$$

where α_i are i -specific intercepts, referred as *fixed effects*.

Adding more variables of the two types, we get the Entity Fixed Effects Regression Model:

$$Y_{it} = \alpha_i + \beta_1 X_{1,it} + \beta_2 X_{2,it} + \dots + \beta_k X_{k,it} + u_{it}.$$

Regression with Panel Data: Time Fixed Effects Regression

Similarly, we can assume that

$$Y_{it} = \beta_0 + \beta_1 X_{it} + \beta_2 Z_t + u_{it},$$

where Z_t is an unobserved variable that depends on t but does not change with i . Therefore, we can rewrite

$$Y_{it} = \lambda_t + \beta_1 X_{it} + u_{it},$$

where λ_t are t -specific intercepts, referred as *time fixed effects*.

Adding more variables of the two types, we get the Time Fixed Effects Regression Model:

$$Y_{it} = \lambda_t + \beta_1 X_{1,it} + \beta_2 X_{2,it} + \dots + \beta_k X_{k,it} + u_{it}.$$

Maximum Likelihood Estimation (MLE)

Maximum likelihood estimation:

Assume that a distribution can be parametrized by $\theta_1, \theta_2, \dots, \theta_d$, then given a sample of i.i.d. $X_1, X_2, \dots, X_n$ from this distribution

$f(x|\theta_1, \theta_2, \dots, \theta_d)$,

the unknown θ_k can be obtained by maximizing the likelihood function:

$$\begin{aligned} L(\theta_1, \theta_2, \dots, \theta_d | X_1, X_2, \dots, X_n) &= \underbrace{f(X_1, X_2, \dots, X_n | \theta_1, \theta_2, \dots, \theta_d)}_{\text{joint distribution}} \\ &= \prod_{k=1}^n f(X_k | \theta_1, \theta_2, \dots, \theta_d). \end{aligned}$$

MLE for Bernoulli Distribution

Example:

Consider a sample of i.i.d. $X_1, X_2, \dots, X_n$ from Bernoulli(p), i.e. the pmf is

$$P(X = k|p) = \begin{cases} p^k(1-p)^{1-k}, & \text{if } k \in \{0, 1\}, \\ 0, & \text{otherwise.} \end{cases}$$

Then the Maximum Likelihood Estimators of p is

$$\hat{p}_{\text{MLE}} = \bar{X}.$$

MLE for Normal Distribution

Example:

Consider a sample of i.i.d. $X_1, X_2, \dots, X_n$ from $\text{Normal}(\mu, \sigma^2)$, i.e. the pdf is

$$f(x|\mu, \sigma^2) = \frac{1}{\sqrt{2\pi}\sigma} e^{-\frac{(x-\mu)^2}{2\sigma^2}}, \quad x \in \mathbb{R},$$

Then the Maximum Likelihood Estimators of μ and σ^2 are

$$\begin{aligned}\hat{\mu}_{\text{MLE}} &= \bar{X}, \\ \hat{\sigma}_{\text{MLE}}^2 &= \frac{1}{n} \sum_{k=1}^n (X_k - \bar{X})^2.\end{aligned}$$

Consistency of MLE

Thm.

Under appropriate smoothness conditions on f , the MLE $\hat{\theta}_n$ from an i.i.d. sample of size n is consistent, that is, for any $\varepsilon > 0$,

$$\lim_{n \rightarrow \infty} P(|\hat{\theta}_n - \theta| > \varepsilon) = 0,$$

where θ denotes the true value of the parameter.

Asymptotic Distribution of MLE

Thm.

Under smoothness conditions on f , as $n \rightarrow \infty$,

$$\sqrt{nI(\theta)}(\hat{\theta} - \theta) \xrightarrow{D} N(0, 1),$$

where θ denotes the true value of the parameter and

$$I(\theta) = -\mathbb{E} \left[\frac{\partial^2}{\partial \theta^2} \ln f(X|\theta) \right].$$

$I(\theta)$ is called *Fisher information*.

Regression with Binary Dependent Variable: Linear Probability Model

Linear Probability Model

Let Y_i be a binary variable. The linear probability model is the following multivariate regression model:

$$Y_i = \beta_0 + \beta_1 X_{i1} + \beta_2 X_{i2} + \dots + \beta_k X_{ik} + u_i \quad \text{with } i \in \{1, 2, \dots, n\}.$$

Regression with Binary Dependent Variable: Linear Probability Model

Linear Probability Model

Let Y_i be a binary variable. The linear probability model is the following multivariate regression model:

$$Y_i = \beta_0 + \beta_1 X_{i1} + \beta_2 X_{i2} + \dots + \beta_k X_{ik} + u_i \quad \text{with } i \in \{1, 2, \dots, n\}.$$

Note that

- $E[Y|X_1, X_2, \dots, X_k] = \beta_0 + \beta_1 X_{i1} + \beta_2 X_{i2} + \dots + \beta_k X_{ik}$, if exogenous.
- $E[Y|X_1, X_2, \dots, X_k] = P(Y = 1|X_1, X_2, \dots, X_k)$.
- $\beta = [\beta_0, \beta_1, \dots, \beta_k]^T$ can be estimated via OLS.
- Errors are always heteroskedastic.
- The slope coefficient β_j is the change in probability of $Y = 1$, given $\Delta X_j = 1$.
- Is predicted probability between 0 and 1? Exogeneity?

 - Linear Probability Model
 - Generalized Linear Model (GLM)
 - GLM: Probit and Logit Regression

Generalized Linear Model (GLM)

The Linear Probability Model,

$$E[Y|X_1, X_2, \dots, X_k] = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \dots + \beta_k X_k,$$

can be generalized via introducing a so called *link function* $g(p)$, which is assumed to be invertible, as follows:

$$E[Y|X_1, X_2, \dots, X_k] = g^{-1}(\beta_0 + \beta_1 X_1 + \beta_2 X_2 + \dots + \beta_k X_k).$$

Generalized Linear Model (GLM)

The Linear Probability Model,

$$E[Y|X_1, X_2, \dots, X_k] = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \dots + \beta_k X_k,$$

can be generalized via introducing a so called *link function* $g(p)$, which is assumed to be invertible, as follows:

$$E[Y|X_1, X_2, \dots, X_k] = g^{-1}(\beta_0 + \beta_1 X_1 + \beta_2 X_2 + \dots + \beta_k X_k).$$

Equivalently,

$$g(E[Y|X_1, X_2, \dots, X_k]) = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \dots + \beta_k X_k.$$

Generalized Linear Model (GLM)

Given Generalized Linear Model

$$E[Y|X_1, X_2, \dots, X_k] = g^{-1}(\beta_0 + \beta_1 X_1 + \beta_2 X_2 + \dots + \beta_k X_k),$$

- $\beta = [\beta_0, \beta_1, \dots, \beta_k]^T$ are estimated via Method of Maximum Likelihood.
- The Maximum Likelihood Estimators (MLE) can be shown to be consistent.
- MLE can be shown to follow normal distribution, if n is large.
- Thus, under assumption of large n , z and F tests can be used.
- If $\Delta X_j = 1$ for some j , while holding other variables fixed, we get

$$\begin{aligned}\Delta \hat{Y} &= E[Y | \dots, X_j + 1, \dots] - E[Y | \dots, X_j, \dots] \\ &= g^{-1}(\beta_0 + \dots + \beta_j(X_j + 1) + \dots + \beta_k X_k) - g^{-1}(\beta_0 + \dots + \beta_j X_j + \dots + \beta_k X_k),\end{aligned}$$

which cannot be simplified further.

Probit and Logit Regression

The GLM

$$E[Y|X_1, X_2, \dots, X_k] = g^{-1}(\beta_0 + \beta_1 X_1 + \beta_2 X_2 + \dots + \beta_k X_k),$$

is called

- Probit if

$$g^{-1}(z) = \Phi(z) \doteq \int_{-\infty}^z \frac{1}{\sqrt{2\pi}} e^{-\frac{t^2}{2}} dt$$

is the cdf of a standard normal random variable. g in this case is called *probit* function and denoted by $\text{probit}(p)$.

- Logit (or Logistic regression) if

$$g^{-1}(z) \doteq \frac{1}{1 + e^{-z}}.$$

In this case, g is called *logit* function and denoted by $\text{logit}(p) = \ln\left(\frac{p}{1-p}\right)$.

Probit and Logit Regression

Example:

```
n = 200
beta0 = -5
beta1 = 10

X = runif(n)
p = inv.logit(beta0 + beta1*X)
Y <- vector()
for (i in 1:n){Y[i] = rbinom(n = 1, size =1, p[i])}
df = data.frame(X,Y)
```

Logit:

```
fit <- glm(Y ~ X, data = df, family = "binomial")
summary(fit)
```

Coefficients:

	Estimate	Std. Error	z value	Pr(> z)	
(Intercept)	-4.7839	0.6559	-7.293	3.02e-13	***
X	9.1660	1.1842	7.740	9.92e-15	***

Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

(Dispersion parameter for binomial family taken to be 1)

Null deviance: 277.18 on 199 degrees of freedom
Residual deviance: 141.43 on 198 degrees of freedom
AIC: 145.43

Number of Fisher Scoring iterations: 5

Probit:

```
fit <- glm(Y ~ X, data = df, family = binomial(link = "probit"))
summary(fit)
```

Coefficients:

	Estimate	Std. Error	z value	Pr(> z)
(Intercept)	-2.8274	0.3494	-8.092	5.89e-16 ***
X	5.4109	0.6214	8.707	< 2e-16 ***

Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

(Dispersion parameter for binomial family taken to be 1)

Null deviance: 277.18 on 199 degrees of freedom
Residual deviance: 139.56 on 198 degrees of freedom
AIC: 143.56

Number of Fisher Scoring iterations: 6
